Project Name: Zenius: The Agentic Workflow Engine for Resilient Team Orchestration

Version: 1.0

1. Project Overview

- **Problem Statement:** Organizations currently rely on fragmented, manual workflows to handle team disruptions. When an employee takes sudden leave or is overwhelmed, task redistribution requires human coordination, often leading to errors, delays, and secondary burnout for the remaining employees.
- **Target Domain:** Intelligent workflow orchestration and adaptive decision-making for administrative and operational processes.
- **Proposed Solution Summary:** Zenius is an AI-powered workflow system using Z.AI's GLM as a central reasoning engine. It ingests unstructured data (chats/emails) to detect absences or burnout and autonomously reassigns tasks based on real-time load maps and skill matching.

2. Background & Business Objective

- **Background of the Problem:** Traditional Project Management (PM) tools are passive repositories of data; they do not "reason" through human emergencies. When "noise" occurs (e.g., an urgent Slack message about a sick child), the workflow breaks until a human manager manually intervenes.
- **Importance of Solving This Issue:** Automated, resilient orchestration prevents project stagnation and protects human capital by ensuring no single member is crushed by redistributed workloads.

- **Strategic Fit / Impact:** Zenius transforms Z.AI's GLM from a simple chatbot into a stateful, adaptive engine that coordinates complex team dynamics.

3. Product Purpose

3.1. Main Goal of the System: To create a resilient team ecosystem where the AI acts as a "Conflict Resolver" and "Orchestrator," maintaining project momentum during human variability.

3.2. Intended Users (Target Audience):

- Project Manager: For "Resilience Reports" and automated oversight.
- Employee: For "Workload Adjustments" and burnout protection.

4. System Functionalities

4.1. Description: The system operates in three layers: Input (Sensors), Reasoning (Logic), and Action (Execution).

4.2. Key Functionalities:

- **Task Extraction:** Transcribing meeting audio/minutes into actionable task lists.
- **Absence Handling:** Detecting leave triggers in chat/email and identifying orphaned tasks.
- **Burnout Prevention:** Flagging members with high loads and stressed sentiment to trigger "Cool-down" periods.
- **Dynamic Reassignment:** Updating project databases and notifying users of new assignees.

4.3. AI Model & Prompt Design

4.3.1. Model Selection: Z.AI GLM is mandatory. It is used for its multi-step reasoning capabilities, enabling it to move from detection to skill-matching and finally to execution.

4.3.2. **Prompting Strategy:** Agentic Multi-step Prompting. The GLM follows a 5-step logic: Detect → Analyze → Match → Check → Execute.

4.3.3. **Context & Input Handling**: The system ingests unstructured data (Slack logs, transcribed minutes). If data is contradictory (e.g., email says "working" but tool shows "no progress"), the GLM triggers a status ping.

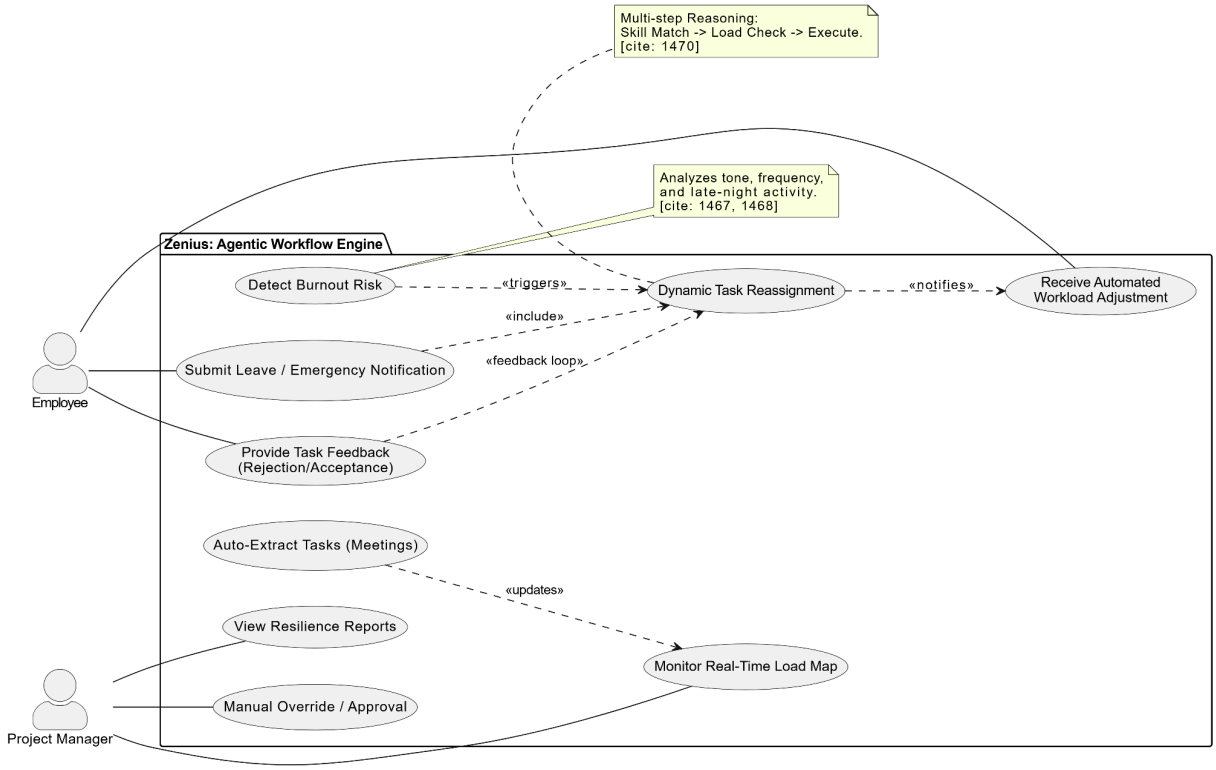
4.3.4. **Fallback & Failure Behavior:** Zenius incorporates Feedback Loops. If a reassigned member rejects a task due to being busy, the GLM re-reasons to find a second-best option.

5. User Stories & Use Cases

- **User Stories:** "As a project leader, I want the system to automatically reassign tasks when a developer is sick, so that our deadline is not missed and no one else is burnt out."
- **Use Cases (Main Interactions): Sudden Leave Interaction**

    1. Sensor detects "urgent leave" keyword in Slack.
    2. Reasoning engine maps current team workloads.
    3. GLM identifies a substitute with matching skills and a load score <80.
    4. Action layer updates the PM tool and sends a "Resilience Report" to the leader.

- **Use Case Diagram:**



6. Features Included (Scope Definition)

- **Real-time Load Map:** Aggregated visualization of team capacity.
- **Sentiment/Burnout Detection:** Analyzing tone and working hours (eg: 3am emails).
- **Structured Actionable Outputs:** Automated Gantt chart updates and documentation generation.

7. Features Not Included (Scope Control)

- **Direct Payroll Integration:** Zenius manages work, not financial compensation.
- **External Client Communication:** Notifications are limited to internal team orchestration.
- **Custom AI Training:** The system uses the pre-trained Z.AI GLM without fine-tuning.

8. Assumptions & Constraints

- **LLM Cost Constraint:** To manage inference costs, repetitive status pings are throttled, and chat logs are summarized before being processed by the GLM.
- **Technical Constraints:** The system requires stable API connections to Gmail.
- **User Input:** The system assumes employees provide accurate "rejection" feedback for the loop to function.

9. Risks & Questions Throughout Development

- **Privacy:** How do we ensure sentiment analysis of private chats respects employee privacy?
- **Conflict Resolution:** What happens if the GLM cannot find any team member with a load score under 80?
- **API Reliability:** If the Z.AI GLM is removed, the system must acknowledge it loses its ability to coordinate the workflow effectively.
